

Early polar spectrin aggregation following CD45RA+ T-cell activation by human dendritic cells. Human dendritic cells derived from macrophage precursors after culture in 1000 U/ml of rGM-CSF and rIL-4 for 7 days were admixed with allogenic T-cells within the peripheral blood mononuclear cells with anti-CD3 for 24 hr and stained with FITC-phalloidin to stain f-actin within the T-cells and DCs. Cells were then stained with rabbit polyclonal anti-spectrin antibody and visualized with a donkey anti-rabbit TRITC. Shown are spectrin aggregates within the activated T-cells, some with uropods primarily distal to the site of DC/T-cell interaction. Other experiments demonstrate that this polarization of T-cell-DC interactions occurs predominantly in naïve CD45RA+ CD4+ cells.
